Any message delivered to another client is already included in the inboxes of all other clients—is that correct? So, if a message is sent to an external source and includes one recipient on the server, all clients on the server will also receive a copy. Is that correct?

Yes, that is correct. Here is exactly how the system handles both scenarios:

---

1. "Any message delivered to another client is already included in the inboxes of all other clients—is that correct?"

- **Intra-Server Group Messages (YES):** Any letter sent from within the server group to another client (or to the main contact point/transmitter) is automatically received in the inboxes of **all** clients in the server group as a group letter. Each client maintains their own independent read receipt and archive status.
- **External Mail Exception (NO):** If an individual client receives mail directly from an **external website** outside the server, only that specific client receives it in their inbox—other clients on the server do not receive copies of external mail addressed solely to that peer.

---

2. "So, if a message is sent to an external source and includes one recipient on the server, all clients on the server will also receive a copy. Is that correct?"

- **YES, absolutely.**
- Because the sender is on the server and at least one destination is a client on the server:
    1. The letter delivered to the local client constitutes an **intra-server group communication** (both sender and target are within the server group).
    2. In the shared SQLite database, that letter is automatically accessible to **all clients on the server** in their inboxes.
    3. All clients on the server will see the **full recipient list** on their copy.
    4. The external source receives its own transmission, which **excludes the internal server recipients** from the visible distribution list.
