What would happen if it was addressed to two at the local server, from an external server? When one person clicked reply, the recipient isn't automatically included in the list. The other recipient would have to be filled in to the form manually. Upon so doing, the message would be revealed to the group. Is that correct?

Yes, that is 100% correct.

Here is the exact step-by-step breakdown of how that scenario operates in the system:

Step-by-Step Flow

1. **Initial Arrival from External Server**:
    - When an external server sends a message addressed to two clients on the local server, the message arrives at their personal inboxes.
    - At this stage, it remains **private** to those recipients—it is not yet visible to the rest of the server group.
2. **Clicking `[ ↩️ Reply ]`**:
    - The `[ ↩️ Reply ]` button targets the **sender** of the message (`sender_url`).
    - Co-recipients are **not** automatically pre-filled into the `To` field.
3. **Manual Addition of the Second Local Recipient**:
    - The user manually adds the other local client to the recipient list (either by selecting their preset name from the *Local Server Client* dropdown or entering their address).
4. **Sending the Reply & Revealing to the Group**:
    - Upon clicking **Send**, the server detects that an inner-server client (or the main contact point) is included in the destination list (`$has_inner_recipient = true`).
    - This immediately triggers the group revelation:
        - **The Original Message** is updated to `shared_with_group = 1`, making it visible in the inboxes/archives of **all** clients on the server with a `[ 👥 Shared External Message ]` badge.
        - **The Reply Message** is dispatched with `shared_with_group = 1`, making the reply visible to **all** clients on the server as well, with the other local client's preset name displayed in the `To:` recipient list.

[!NOTE] Requiring the user to manually add the local recipient keeps the revelation to the group an **intentional action**—ensuring external communications aren't unintentionally

broadcast to the entire group unless explicitly looped in. If you'd ever like a dedicated `[ ↩️ Reply All ]` button alongside `[ ↩️ Reply ]`, we can easily add that as well!
