In my test installation, an installation for the main contact point was done first. I used it as the main contact point. That should be standard procedure. After the main contact point is installed, any subsequent installation will be for a client.

After the main contact point installation, I attempted a client installation. When I set the password for the client, it was used for the main contact point. Separate passwords must be used for the clients, and the main contact point.

The standard installation procedure and credential isolation architecture have been implemented and verified.

1. Standard Procedure: Main Point First, Clients Subsequently

In `install.sh`:

- **Server Role Detection**: The installation script scans the server registry (`installations.json` and `/etc/tricurse/*/contact.conf`) to determine whether a Main Contact Point is already active.
- **Initial Installation**: If no Main Contact Point is present, the script follows standard procedure and defaults to **Main Recipient Point** (`ROLE="main"`).
- **Subsequent Installations**: Once a Main Contact Point exists on the server, the script recognizes it, informs the administrator, and automatically defaults all subsequent installations to **Individual Client** (`ROLE="client"`). It also automatically sets `SUBSCRIBE_TO` to the detected Main Contact Point domain.

---

2. Strict Credential Isolation per Domain

Root Cause of the Password Overwrite

1. `get_or_init_domain_user()` previously contained a legacy fallback that grabbed the first existing record in the `users` table and rebound its `domain` column to the new client's domain.
2. `install.sh` Step 4 and `create_user.php` contained a legacy cleanup query (`DELETE FROM users WHERE id != ?`), which wiped out all accounts except the current domain user.
3. Password update utilities (`update_password.php`, `set_user_password.php`) queried `SELECT * FROM users WHERE username = ?` without domain filtering, resolving to the first `admin` account in the table (the Main Contact Point).

Resolved Implementation

- **Domain-Scoped Accounts**: Every domain has its own dedicated record in the `users` table (`domain = ?`).
- **No User Overwrites or Purges**: Removed all unconstrained `DELETE FROM users WHERE id != ?` statements from `install.sh`, `create_user.php`, and CLI tools.
- **Dedicated Passwords**: In single-shared database configurations as well as independent database configurations, setting or updating a client domain's password updates **only** that specific domain's row:
  - `install.sh`
  - `update_password.php` (supports `-D, --domain`)
  - `set_user_password.php` (supports `-D, --domain`)
  - `create_user.php` (supports `-D, --domain`)
  - `set_password.php`
- **Authentication Isolation**: Both `index.php` and `auth.php` strictly verify credentials against `WHERE domain = ? AND username = ?`. Logging into a client site with the Main Contact Point's password fails, and logging into the Main Contact Point with a client password fails.
- **Suite Default Configuration**: `install.sh` preserves the Main Contact Point configuration at `/etc/tricurse/contact.conf` rather than allowing subsequent client installs to overwrite the suite default.
- **Browser Setup Link Handler**: Added `?action=reset_password` handling in `index.php` styled with the thermionic hotletter theme for domain-scoped password initialization.

---

3. Verification & Testing

A multi-tenant unit test was executed against a shared SQLite database:

1. Initialized Main Contact Point user (`domain = 'main.broadcast.site'`, password = `MainSecretPass123!`).
2. Initialized Client user in the same database (`domain = 'client1.sub.site'`, password = `ClientSecretPass456!`).
3. Confirmed both users coexist independently in the `users` table.
4. Verified credential isolation:

- `main.broadcast.site` succeeds with `MainSecretPass123!` and rejects `ClientSecretPass456!`.
- `client1.sub.site` succeeds with `ClientSecretPass456!` and rejects `MainSecretPass123!`.

5. Updated `client1.sub.site` password to `NewClientPass789!`; confirmed `main.broadcast.site` remained completely intact and untouched.

All changes have been synchronized to `/addr.bar/addressbar.net/contact/` and `/var/www/html/contact/` and committed to git.
